Earth-moving: Construction fill areas:	(1b)	Maintain soil moisture content at a minimum of 12 percent, as determined by ASTM method D-2216, or other equivalent method approved by the Executive Officer, the California Air Resources Board, and the U.S. EPA. For areas which have an optimum moisture content for compaction of less than 12 percent, as determined by ASTM Method 1557 or other equivalent method approved by the Executive Officer and the California Air Resources Board and the U.S. EPA, complete the compaction process as expeditiously as possible after achieving at least 70 percent of the optimum soil moisture content. Two soil moisture evaluations must be conducted during the first three hours of active operations during a calendar day, and two such evaluations during each subsequent four-hour period of active operations.

# DRAFT ENVIRONMENTAL IMPACT REPORT APPENDIX C

**HEALTH RISK ASSESSMENT** 

#### Memorandum

TO: Shannon Daniels

**AECOM** 

FROM: Sam Silverman, Senior Environmental Scientist

DATE: April 22, 2010

RE: Echo Park Lake Rehabilitation Project Construction Health Risk Assessment

Terry A. Hayes Associates LLC (TAHA) completed an Air Quality and Noise Impact Report for the Echo Park Rehabilitation Project. As a supplement to this Report, TAHA completed a health risk assessment (HRA) for construction activity associated with the proposed project. The results of the HRA are presented in this memorandum, and included in the Air Quality and Noise Impact Report.

#### Methodology

The HRA was prepared based on emissions from haul trucks and diesel-powered construction equipment. The first step was to calculate the mass emissions from these sources. The proposed project would generate 8,858 truck trips during the construction phase. On-road truck emissions were calculated based on the haul route from the project site to US Highway 101 and emission rates from the EMFAC2007 model. It was assumed that each truck would idle on the project site for 15 minutes, and the idle emission rate was also obtained from the EMFAC2007 model. Equipment emissions were obtained from the OFFROAD model. It was assumed that ten pieces of equipment would operate on the project site.

The truck and equipment emission rates were input into the AERMOD dispersion model to obtain annual exposure concentrations. The model is a steady state Gaussian plume model for estimating ground level impacts from point, area, and volume sources in simple and complex terrain. The model offers additional flexibility by allowing the user to assign initial vertical and lateral dispersion parameters for stationary sources. Truck emissions were modeled based on the South Coast Air Quality Management District (SCAQMD) Health Risk Assessment Guidance for Analyzing Cancer Risks from Mobile Source Diesel Idling Emissions for CEQA Air Quality Analysis (August 2003). Idle emissions were treated as an area source with a five-meter release height. On-road emissions along the haul route were input as a line source with a release height of five meters.

Shannon Daniels April 22, 2010 Page 2

Construction equipment emissions were modeled based on guidance from the SCAQMD Localized Significance Methodology. Equipment emissions were input as an area source with a release height of five meters. Based on SCAQMD guidance, a 50-meter receptor grid was used to obtain the maximum annual pollutant concentration and the receptor release height was set at 0.0 meters. AERMOD utilized surface meteorological and upper air data from the Downtown Los Angeles station.

#### **Risk Characterization**

Carcinogenic compounds are not considered to have threshold levels (i.e., dose levels below which there are no risks). Any exposure, therefore, will have some associated risk. As a result, the State of California has established a threshold of one in one hundred thousand (1.0E-05) as a level posing no significant risk for exposures to carcinogens regulated under the Safe Drinking Water and Toxic Enforcement Act (Proposition 65).

Health risks associated with exposure to carcinogenic compounds can be defined in terms of the probability of developing cancer as a result of exposure to a chemical at a given concentration. Under a deterministic approach (i.e., point estimate methodology), the cancer risk probability is determined by multiplying the chemical's annual concentration by its unit risk factor (URF). The URF is a measure of the carcinogenic potential of a chemical when a dose is received through the inhalation pathway. It represents an upper bound estimate of the probability of contracting cancer as a result of continuous exposure to an ambient concentration of one microgram per cubic meter ( $\mu$ g/m³) over a 70-year lifetime.

The carcinogenic risk was calculated based on the SCAQMD Health Risk Assessment Guidance for Analyzing Cancer Risks from Mobile Source Diesel Idling Emissions for CEQA Air Quality Analysis. According to this document, the cancer risks from diesel particulate matter associated with motor vehicles occur exclusively through the inhalation pathway. Therefore, the cancer risks can be estimated from the following equation:

 $CR_{DPM} = C_{DPM} \times URF_{DPM} \times LEA$ 

where,

CR<sub>DPM</sub> Cancer risks from diesel particulate matter; the probability of an individual developing

cancer as a result of exposure to diesel particulate matter.

 $C_{DPM}$  Annual average diesel particulate matter concentration in  $\mu g/m^3$ .

URF<sub>DPM</sub> Unit risk factor for diesel particulate matter; estimated probability that a person will

contract cancer as a result of inhalation of a diesel particulate matter concentration of 1

µg/m<sup>3</sup> continuously over a period of 70 years.

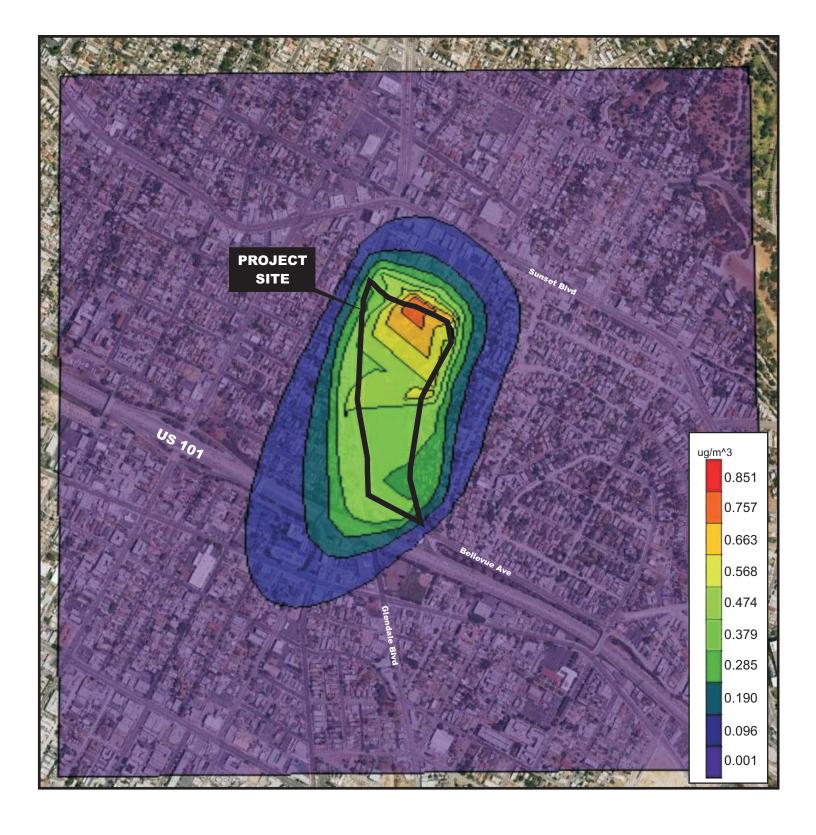

LEA Lifetime exposure adjustment.

The URF utilized in the assessment and corresponding cancer potency factors was obtained from California Office of Environmental Health Hazard Assessment (OEHHA) guidance. The LEA accounts for the fact that exposure would be less than 70 years. Based on information provided by the Applicant, the exposure level was adjusted to account for 10 hours per day, 5 days per week, 48 weeks per year, and 2 years.

Shannon Daniels April 22, 2010 Page 3

#### **Results**

**Figure 1** is a contour map showing exposure concentrations to diesel particulate matter generated during construction activity. The maximum off-site annual concentration would be 0.85 micrograms per cubic meter. This results in a carcinogenic risk of 2.2 persons in one million, which is less than the ten persons in one million significance threshold. Construction-related diesel emissions would result in a less-than-significant impact.
